

Patent Claims:

1 1. Cross spring element for the connection of two relatively
2 rotatable bearing elements (1, 2), that comprises at least
3 two leaf spring elements (3, 4, 5, 6) which cross each
4 other transversely to the rotation axis (7) and which
5 connect both bearing elements (1, 2) with one another,
6 characterized in that the mutually crossing leaf spring
7 elements (3, 4; 5, 6) of one radial direction (8) are
8 arranged at least pair-wise, whereby the ends of each leaf
9 spring pair (3, 4; 5, 6) on one side are respectively
10 secured to different bearing elements (1, 2), and this
11 alternately with the opposite side.

1 2. Cross spring element according to claim 1, characterized in
2 that the bearing elements (1, 2) are embodied ring-shaped
3 and are connected with four pair-wise crossing leaf springs
4 (3, 4; 5, 6), whereby the leaf spring pairs (3, 4; 5, 6)
5 cross themselves orthogonally.

1 3. Cross spring element according to claim 1 or 2,
2 characterized in that the leaf springs (3, 4, 5, 6) are
3 arranged parallel next to one another in the direction of
4 the rotation axis (7) and cross themselves on the rotation
5 axis (7).

1 4. Cross spring element according to one of the preceding
2 claims, characterized in that the ring-shaped bearing

elements (1, 2) comprise an outwardly directed planar connection rim (11) for the securing of a rotation element, and an inwardly stepped inner part (12) provided with projections and recesses (13), which engage into the oppositely lying bearing element (1, 2) and have at least axial surfaces (9) for the securing of the leaf spring ends.

5. Cross spring element according to one of the preceding claims, characterized in that the ring-shaped bearing elements (1, 2) are axially spaced from one another by recesses (13) or slits, and permit at least a twisting or rotation angle of 5° up to 45° , and are connected through flat thin leaf springs (3, 4, 5, 6), whereby the leaf springs (3, 4, 5, 6) are flexurally soft in the rotation direction and flexurally hard in the tension direction.

6. Cross spring element according to one of the preceding claims, characterized in that the ring-shaped bearing elements (1, 2) comprise securing means, with the aid of which this is rotatably supported between a drive unit and a force transducer, and serves for the friction-free transmission of the drive moment that is to be measured.

7. Cross spring element according to claim 6, characterized in that this is arranged between a drive shaft of an impeller wheel and a force transducer of a bulk material mass flow measuring apparatus according to the Coriolis principle.
